

## SolarMax Energy Systems

# Double glass single glass monocrystalline silicon components

## Overview

---

silicon is generally created by one of several methods that involve melting high-purity, semiconductor-grade silicon (only a few parts per million of impurities) and the use of a to initiate the formation of a continuous single crystal. This process is normally performed in an inert atmosphere, such as argon, and in an inert crucible, such as , to avoid impurities that would affect the crystal uniformity.

What is a monocrystalline silicon solar cell?

Monocrystalline silicon solar cells involve growing Si blocks from small monocrystalline silicon seeds and then cutting them to form monocrystalline silicon wafers, which are fabricated using the Czochralski process (Figure 4 a). Monocrystalline material is widely used due to its high efficiency compared to multicrystalline material.

How is monocrystalline silicon formed?

Monocrystalline silicon is generally created by one of several methods that involve melting high-purity, semiconductor-grade silicon (only a few parts per million of impurities) and the use of a seed to initiate the formation of a continuous single crystal.

Are double-glass solar modules reactive or non-reactive?

Furthermore, comparing to plastic backsheets (the back material of single-glass solar module) which are reactive, glass is non-reactive. This means that the whole structure of Raytech double-glass solar modules (two layers of glass and one layer of solar cells in the middle) are highly resistant to chemical reactions such as corrosion as a whole.

What is monocrystalline silicon used for?

Monocrystalline silicon is also used for high-performance photovoltaic (PV) devices. Since there are less stringent demands on structural imperfections compared to microelectronics applications, lower-quality solar-grade silicon (Sog-Si) is often used for solar cells.

What is the difference between Raytech double glass solar modules?

Whereas for Raytech double-glass solar modules, with the increased strength brought by two layers of glass, a lot less deformation will happen in the solar cells, the possibility of microcracks formed on the solar cells will decrease significantly.

Why are solar cells dominated by monocrystalline silicon?

It is noted that the solar cell market is dominated by monocrystalline silicon cells due to their high efficiency. About two decades ago, the efficiency of crystalline silicon photovoltaic cells reached the 25% threshold at the laboratory scale. Despite technological advances since then, peak efficiency has now increased very slightly to 26.6%.
